A VEHICLE ALTERNATOR HAVING A WINDING INSULATED FROM ITS

CASE

BACKGROUND OF THE INVENTION

The present invention relates to alternators or to alternator-starters.

A vehicle alternator is known that comprises a case, a stator winding, and a solidified electrically-insulating varnish impregnating the end turns and the twisted leads of the winding so as to insulate them electrically from the adjacent case and so as to reinforce their mechanical strength. The neutral points of the winding is insulated in the same manner. Nevertheless, when subjected to the vibration due to operation, there is a major risk of the varnish being abraded and thus of the electrical insulation of the end turns, the twisted leads, and the neutral point disappearing.

Document US-4 658 164 discloses a vehicle alternator in which an electrically-insulating screen is provided in the form of a separate piece extending between the stator winding and the case. That avoids the risk of abrasion. However, that document provides for the twisted leads to be returned along the screen and complicates connection thereof.

BRIEF SUMMARY OF THE INVENTION

An object of the invention is to ensure that the insulating protection is long-lasting without complicating the connection of the twisted leads.

To achieve this object, the invention provides a vehicle alternator comprising a case, a stator winding, and an electrically-insulating element interposed between the case and the winding, the insulating element being a solid body mounted on one of the case and the winding, wherein the insulating element has at least one duct extending through an orifice in the case.

There is thus no risk of abrasion of the insulating element and as a result the protection is long-lasting.

In addition, the duct can receive a twisted lead of live outlet wires from the winding, which twisted lead is

35

Thus, the angular position of the stator about its axis is identified, making it easier to install, and guaranteeing that the twisted leads of live wires are properly positioned relative to the case, and in particular relative to the orifices therein.

Advantageously, the case has a second indexing portion, in particular a groove, suitable for co-operating with the indexing portion of the insulating element.

5       The invention also provides a method of manufacturing a vehicle alternator comprising a case, a stator winding, and an electrically-insulating element interposed between the case and the winding, wherein: the insulating element is supplied in the form of a solid  
10       body having at least one duct; the insulating element is mounted on one of the case and the winding; and the duct is inserted through an orifice in the case.

Advantageously, the insulating element is mounted on the winding.

15       Advantageously, the insulating element is mounted on the case.

#### BRIEF DESCRIPTION OF THE DRAWINGS

^ Other characteristics and advantages of the invention will appear on reading the following description of a preferred embodiment and of a variant given as non-limiting examples. In the accompanying  
20       drawings:

- Figure 1 is a fragmentary axial section view of an alternator of the invention showing the stator and the case;

25       - Figures 2 and 3 are two perspective views from above and from below of the insulating element of Figure 1;

30       - Figures 4 and 5 are two views analogous to Figure 1 showing a variant embodiment, respectively level with one of the twisted leads of live wires and level with the neutral point; and

- Figures 6 and 7 are two views analogous to Figures 2 and 3, showing the insulating element of

Figures 4 and 5.

#### DETAILED DESCRIPTION OF THE INVENTION

35 ^ ~~With reference to Figures 1 to 3, the alternator 2 comprises in conventional manner a shaft of axis 5 and a case of which only a shell 4 is shown herein. The shell~~

cancel.*

5 ~~has a plane rear wall 6 perpendicular to the axis 5~~  
forming a rear plate with a bearing for the shaft, and a  
cylindrical side wall 8 about the axis 5. The shell is  
closed by a cover that forms a front bearing and that is  
not shown. The alternator has a stator 10 comprising a  
stack of laminations 12 on which a winding 14 is wound.  
The wires of the winding are received in slots (not  
shown) in the stack of laminations 12 extending parallel  
to the axis. The winding 14 has end turns that emerge  
10 through the rear axial end of the stack of laminations  
12. This winding has twisted leads 16 of live wires, in  
this case three such leads since the winding is a so-  
called "single" winding. The twisted leads 16 emerge  
~~from a rear axial end face of the winding 14.~~

15 In accordance with the invention, the alternator has  
an electrically-insulating element 18 which is  
constituted in this case by a single piece of plastics  
material. This element 18 is generally annular in shape  
about the axis 5. Its section in a plane radial to the  
20 axis 5 is in the form of a channel section defining a  
plane web or rear axial end wall 20 and two flanges or  
cylindrical side walls about the axis 5, comprising an  
outer flange 22 and an inner flange 24 that face each  
other. The insulating element 18 has three cylindrical  
25 ducts 26 extending with axes parallel to the axis 5 so as  
to project from the web 20 away from the flanges 22 and  
24. The three ducts 26 are close to one another around  
the axis 5.

30 The outer flange 22 carries a stud 28 extending  
radially outwards. The side wall 8 of the shell has an  
inside groove 30 extending parallel to the axis 5 and  
suitable for receiving the stud 28 when the stator is  
mounted in the case. In Figure 1, the stud 28 and the  
groove 30 are shown as lying in the section plane of the  
35 figure for greater clarity, however the preferred  
position for the stud 28 (and thus for the groove 30) is  
as shown in Figure 3.

09486790-062600

During assembly of the alternator, the stator is built and the insulating element 18 that has previously been made by molding is mounted coaxially on the winding 14, being placed over its end turns and with its three twisted leads 16 being inserted into the three ducts 26 respectively. As a result, the insulating element 18 covers the inner and outer faces and the axial end face of the end turns. The edges of the insulating element 18 come into axial abutment against the stack of laminations 12. Thereafter, the stator 10 is mounted inside the shell 4. Having the stud 28 received in the groove 30 then makes it possible to ensure that the stator 10 is properly positioned relative to the shell 4 and angularly about the axis 5 so that the twisted leads 16 and the ducts 26 are in register with orifices 32 formed through the rear wall 6 of the shell, and then penetrate through said orifices 32. Once assembly has been completed, the insulating element 18 is interposed axially between the end wall 6 and the winding 14, and radially between the side wall 8 and the winding 14. In addition, it extends in register with an inside side face of the winding. This ensures that the end turns and the twisted leads are electrically insulated from the case 4, including where they pass through the orifices 32.

In the variant of Figures 4 to 7, the winding 14 is identical to that of Figure 1, except that the twisted leads 16 have been offset so as to project from the winding in a radial direction towards the axis 5. Consequently, the ducts 26 are likewise formed to project from the inner flange 24 of the insulating element 18 so as to receive the twisted leads 16 in this configuration. In addition, the live wire twisted leads 16 are six in number in this embodiment since the winding is said to be "double". There are thus also six ducts 26. The neutral points 34 of the winding 14 is shown in Figure 5.

It is possible to mount the insulating element 18 in the shell 4 prior to fitting the stator 10 thereon.

009290" 06293460

The insulating element 18 can be built up from a plurality of parts fixed to one another prior to being fitted to the alternator.
